Relevance logic: syntax, relevance frames

The language of **propositional relevance logic** \mathcal{L}_R over a fixed set of propositional variables VAR is given by

$$A = p \mid \perp \mid \top \mid \mathbf{t} \mid \sim A \mid (A \wedge A) \mid (A \vee A) \mid (A \circ A) \mid (A \rightarrow A)$$

A **relevance frame** is a tuple $\mathcal{F} = \langle W, O, R, * \rangle$, where:

- W is a non-empty set of states (possible worlds);
- $O \subseteq W$ is the subset of **normal** states;
- $R \subseteq W^3$ is a **relevant accessibility relation**;
- $* : W \rightarrow W$ is a function, called the **Routley star**, used to provide semantics for \sim .

Relevance logic: Routley-Meyer frames

The following binary relation \preceq is defined in every relevance frame:

$$u \preceq v \text{ iff } \exists o(o \in O \wedge Rouv)$$

A **Routley-Meyer frame** (or **RM-frame**) is a relevance frame satisfying the following conditions for all $u, v, w, x, y, z \in W$:

- 1 $x \preceq x$
- 2 If $x \preceq y$ and $Ryuv$ then $Rxuv$.
- 3 If $x \preceq y$ and $Ruyv$ then $Ruxv$.
- 4 If $x \preceq y$ and $Ruvx$ then $Ruvy$.
- 5 If $x \preceq y$ then $y^* \preceq x^*$.
- 6 O is upward closed w.r.t. \preceq ,
i.e. if $o \in O$ and $o \preceq o'$ then $o' \in O$.

$\therefore \preceq$ is a preorder.

Adding a valuation $V : \text{VAR} \rightarrow \mathcal{P}^\uparrow(W)$ produces a **Routley-Meyer model**

$$\mathcal{M} = \langle W, O, R, *, V \rangle$$

Relevance logic: Relational Semantics

Truth of a formula A in a RM-model $\mathcal{M} = \langle W, O, R, *, V \rangle$ at a state $u \in W$, denoted $\mathcal{M}, u \Vdash A$, is defined as follows:

- $\mathcal{M}, u \Vdash p$ iff $u \in V(p)$;
- $\mathcal{M}, u \Vdash \mathbf{t}$ iff $u \in O$;
- $\mathcal{M}, u \Vdash \sim A$ iff $\mathcal{M}, u^* \not\Vdash A$;
- $\mathcal{M}, u \Vdash A \wedge B$ iff $\mathcal{M}, u \Vdash A$ and $\mathcal{M}, u \Vdash B$;
- $\mathcal{M}, u \Vdash A \vee B$ iff $\mathcal{M}, u \Vdash A$ or $\mathcal{M}, u \Vdash B$;
- $\mathcal{M}, u \Vdash A \rightarrow B$ iff for every v, w such that $Ruvw$, if $\mathcal{M}, v \Vdash A$ then $\mathcal{M}, w \Vdash B$.
- $\mathcal{M}, u \Vdash A \circ B$ iff there exist v, w such that $Rvwu$, $\mathcal{M}, v \Vdash A$ and $\mathcal{M}, w \Vdash B$.

Relevance logic: Algebraic Semantics

A structure $\mathbb{A} = \langle A, \wedge, \vee, \circ, \rightarrow, \sim, \mathbf{t}, \top, \perp \rangle$ is called a **relevant algebra** [Urquhart, 1996] if it satisfies the following conditions:

- 1 $\langle A, \wedge, \vee, \top, \perp \rangle$ is a bounded distributive lattice,
- 2 $a \circ (b \vee c) = (a \circ b) \vee (a \circ c)$,
- 3 $(b \vee c) \circ a = (b \circ a) \vee (c \circ a)$,
- 4 $\sim(a \vee b) = \sim a \wedge \sim b$,
- 5 $\sim(a \wedge b) = \sim a \vee \sim b$,
- 6 $\sim \top = \perp$ and $\sim \perp = \top$,
- 7 $a \circ \perp = \perp \circ a = \perp$,
- 8 $\mathbf{t} \circ a = a$, and
- 9 $a \circ b \leq c$ iff $a \leq b \rightarrow c$.

An \mathcal{L}_R -formula ϕ is **valid** on a relevant algebra \mathbb{A} if the inequality $\mathbf{t} \leq \phi$ is valid on \mathbb{A} .

Some well-known correspondences for Relevance Logic [Routley, Plumwood, Meyer, Brady, 1982]

	Axiom	Correspondent on RM-frames
B1.	$A \wedge (A \rightarrow B) \rightarrow B$	$Raaa$
B6.	$A \rightarrow ((A \rightarrow B) \rightarrow B)$	$Rabc \Rightarrow Rbac$
B10.	$A \rightarrow (B \rightarrow B)$	$Rabc \Rightarrow b \leq c$
B11.	$B \rightarrow (A \rightarrow B)$	$Rabc \Rightarrow a \leq c$
B13.	$A \rightarrow (B \rightarrow A \wedge B)$	$Rabc \Rightarrow a \leq c \ \& \ b \leq c$
B19.	$A \vee B \rightarrow ((A \rightarrow B) \rightarrow B)$	$Rabc \Rightarrow (Rbac \ \& \ a \leq c)$
D2.	$A \vee \sim A$	$0^* \leq 0$
D3.	$(A \rightarrow \sim A) \rightarrow \sim A$	Raa^*a
D4.	$(A \rightarrow \sim B) \rightarrow (B \rightarrow \sim A)$	$Rabc \Rightarrow Rac^*b^*$

Extensions of **B** with there axioms are sound complete w.r.t. corresponding classes of RM-frames.

Modal Correspondence (and Canonicity) Theory

- Sahlqvist-van Benthem class (mid 1970's)
- Many, many extensions and variations subsequently.
- Purely algebraic proof of canonicity of Sahlqvist-van Benthem formulas [Jönsson, 1994]
- Canonicity-via-correspondence approach [Sambin, Vacarro, 1989].
- Sahlqvist theory for distributive modal logic [Gehrke, Nagahashi, Venema, 2005]
- Extension to **inductive formulas** [Goranko, Vakarelov, 2006]
- Classical Algorithmic correspondence, SQEMA [C, Goranko, Vakarelov, 2006]
- 'Unified Correspondence' [C, Palmigiano 2012, 2019], [C, Ghilardi, Palmigiano, 2014]

Relevant Correspondence (and Canonicity) Theory

“Correspondence theory in the case of modal and intuitionistic logic has been extensively studied, but the analogous theory for the case of relevant logics is surprisingly neglected.” – Urquhart, 1996

Precursors:

- A Sahlqvist theorem for relevant modal logics [Seki, 2003]
- On Sahlqvist formulas in relevant logic [Badia, 2018]

Current work:

- Within the Unified Correspondence framework:
 - Definition of Inductive and Sahlqvist formulas for Relevance Logic
 - Calculus or rewrite rules (specializing ALBA)
- PEARL algorithm = Calculus + Relevance Logic-specific translation + simplification
- Implementation of PEARL

PEARL algorithm

Extended language:

$$\phi = p \mid \mathbf{i} \mid \mathbf{m} \mid \top \mid \perp \mid \mathbf{t} \mid \sim\phi \mid (\phi \wedge \phi) \mid (\phi \vee \phi) \mid (\phi \circ \phi) \mid (\phi \rightarrow \phi) \mid \sim^b\phi \mid \sim^\# \phi \mid (\phi \prec \phi) \mid (\phi \Rightarrow \phi) \mid (\phi \hookrightarrow \phi)$$

where $p \in \text{VAR}$, $\mathbf{i} \in \text{NOM}$ and $\mathbf{m} \in \text{CNOM}$.

Applies calculus of rewrite rules to eliminate propositional variables in favour of nominals and co-nominals.

If successful, translate into first-order logic and simplify.

PEARL calculus: Ackermann-rules

$$\frac{\alpha \leq p, \Delta(p) \implies \gamma(p) \leq \beta(p)}{\Delta(\alpha/p) \implies \gamma(\alpha/p) \leq \beta(\alpha/p)} \text{ (RAR)}$$

$$\frac{p \leq \alpha, \Gamma(p) \implies \beta(p) \leq \gamma(p)}{\Gamma(\alpha/p) \implies \beta(\alpha/p) \leq \gamma(\alpha/p)} \text{ (LAR)}$$

The Right Ackermann-rule (RAR) and Left Ackermann-rule (LAR) are subject to the following conditions:

- p does not occur in α ,
- β is positive in p ,
- γ is negative in p ,
- Γ is negative in p ,
- Δ is positive in p ,

PEARL calculus: Monotone variable elimination rules

$$\frac{\Gamma(p) \implies \gamma(p) \leq \beta(p)}{\Gamma(\top/p) \implies \gamma(\perp/p) \leq \beta(\perp/p)} (\perp) \quad \frac{\Delta(p) \implies \beta(p) \leq \gamma(p)}{\Delta(\perp/p) \implies \beta(\top/p) \leq \gamma(\top/p)} (\top)$$

provided that $\beta(p)$ and Γ are positive in p , while $\gamma(p)$ and $\Delta(p)$ are negative in p .

PEARL calculus: Approximation rules (sample)

$$\frac{\Gamma \implies \phi \leq \psi}{\mathbf{j} \leq \phi, \psi \leq \mathbf{m}, \Gamma \implies \mathbf{j} \leq \mathbf{m}}$$

where \mathbf{j} is a nominal and \mathbf{m} is a co-nominal not occurring in the premise.

$$\frac{\chi \rightarrow \phi \leq \mathbf{m}, \Gamma \implies \alpha \leq \beta}{\mathbf{j} \leq \chi, \mathbf{j} \rightarrow \phi \leq \mathbf{m}, \Gamma \implies \alpha \leq \beta} (\rightarrow\text{Appr-Left})$$

$$\frac{\mathbf{i} \leq \chi \circ \phi, \Gamma \implies \alpha \leq \beta}{\mathbf{j} \leq \chi, \mathbf{i} \leq \mathbf{j} \circ \phi, \Gamma \implies \alpha \leq \beta} (\circ\text{Appr-Left})$$

$$\frac{\sim\phi \leq \mathbf{m}, \Gamma \implies \alpha \leq \beta}{\phi \leq \mathbf{n}, \sim\mathbf{n} \leq \mathbf{m}, \Gamma \implies \alpha \leq \beta} (\sim\text{Appr-Left})$$

where \mathbf{j} a nominal and \mathbf{n} is a co-nominal not appearing in the premises.

PEARL calculus: Residuation rules

$$\frac{\phi \leq \chi \vee \psi, \Gamma \implies \alpha \leq \beta}{\phi \multimap \chi \leq \psi, \Gamma \implies \alpha \leq \beta} (\vee\text{Res})$$

$$\frac{\phi \wedge \chi \leq \psi, \Gamma \implies \alpha \leq \beta}{\phi \leq \chi \implies \psi, \Gamma \implies \alpha \leq \beta} (\wedge\text{Res})$$

$$\frac{\phi \leq \chi \rightarrow \psi, \Gamma \implies \alpha \leq \beta}{\phi \circ \chi \leq \psi, \Gamma \implies \alpha \leq \beta} (\rightarrow\text{Res})$$

$$\frac{\psi \leq \phi \multimap \chi, \Gamma \implies \alpha \leq \beta}{\phi \circ \psi \leq \chi, \Gamma \implies \alpha \leq \beta} (\multimap\text{Res})$$

PEARL calculus: Adjunction rules

$$\frac{\phi \vee \chi \leq \psi, \Gamma \implies \alpha \leq \beta}{\phi \leq \psi, \chi \leq \psi, \Gamma \implies \alpha \leq \beta} (\vee\text{Adj})$$

$$\frac{\psi \leq \phi \wedge \chi, \Gamma \implies \alpha \leq \beta}{\psi \leq \phi, \psi \leq \chi, \Gamma \implies \alpha \leq \beta} (\wedge\text{Adj})$$

$$\frac{\sim \phi \leq \psi, \Gamma \implies \alpha \leq \beta}{\sim^b \psi \leq \phi, \Gamma \implies \alpha \leq \beta} (\sim\text{Left-Adj})$$

$$\frac{\phi \leq \sim \psi, \Gamma \implies \alpha \leq \beta}{\psi \leq \sim^\# \phi, \Gamma \implies \alpha \leq \beta} (\sim\text{Right-Adj})$$

Implementation of PEARL

The input is a \LaTeX string using the standard syntax of relevance logic expressions.

Intuitionistic implication \Rightarrow , coimplication \Leftarrow , the right residual \Leftarrow of \circ , and the adjoints $\sim^{\#}$ and \sim^{\flat} can also appear in an input formula.

The expression is parsed with a simple top-down Pratt parser [1973] using standard rules of precedence.

For well-formed formulas, an abstract syntax tree (AST) based on Python dictionaries and lists of arguments is created for each formula.

Parsing example

E.g., the formula $A = "p \rightarrow q \wedge \mathbf{t}"$ is translated to the AST representation

```
A={ "id": "\to", "a": [
  { "id": "p", "a": [] },
  { "id": "\\land", "a": [
    { "id": "q", "a": [] },
    { "id": "\mathbf t", "a": [] }
  ] }
]}
```

The implication symbol \rightarrow is referenced by `A.id`

and the two arguments are `A.a[0]` and `A.a[1]`.

Preprocessing phase

Five short recursive Python functions are used to transform the AST representation step-by-step according to the specific groups of PEARL transformation rules.

The function `preprocess(st)` takes a \LaTeX string `st` as input and parses it, producing an AST A .

If the formula A is not well-formed, an error-string is returned.

If it has a top-level \rightarrow symbol, it is replaced with a \leq to turn the formula into an inequality, and otherwise the equivalent inequality $\mathbf{t} \leq A$ is constructed.

Subsequently the splitting rules and monotonicity rules are applied and the resulting list of inequalities is returned.

Preprocessing example

For example, with $p \rightarrow q \wedge \mathbf{t}$ as input, the formula is parsed, rewritten as $p \leq q \wedge \mathbf{t}$

The splitting rules produce the list $[p \leq q, p \leq \mathbf{t}]$ and monotonicity returns $[\top \leq \perp, \top \leq \mathbf{t}]$.

The function `approximate(As)` takes this list as input, and applies the first approximation rule to each formula, followed by all possible left and right approximations interleaved with further applications of the splitting rule.

The result is a list of quasi-equations that always have conclusion $\mathbf{i} \leq \mathbf{m}$ and premises that are irreducible with respect to the approximation and splitting rules.

Elimination phase

The function `eliminate(As)` then attempts to apply the Ackermann-rules to each quasi-equations by selecting each variable, first with positive polarity and, if that does not succeed, then with negative polarity.

Backtracking is used to ensure that all variables are tried in all possible orders.

If for some quasi-equations none of the variable orders allow all variables to be eliminated, then the function reports this result.

On the other hand, if for each quasi-equations some variable order succeeds to eliminate all formula variables then the resulting list of pure quasi-equations (i.e., containing no formula variables, but only nominals or co-nominals) is returned.

Simplification phase

Since these pure quasi-equations contain redundant premises, the function $\text{simplify}(As)$ is used to eliminate them, and to also apply the left and right simplification rules.

Finally the variant of the standard translation is applied to the pure quasi-equations and produces a first-order formula on the Routley-Meyer frames.

Translation rules (Part 1)

- $\text{Tr}(\mathbf{i} \leq \mathbf{j}) = x_j \preceq x_i$
- $\text{Tr}(\mathbf{i} \leq \mathbf{m}) = x_i \not\preceq y_m$
- $\text{Tr}(\mathbf{i} \leq \mathbf{t}) = O_{x_i}$
- $\text{Tr}(\mathbf{i} \leq \perp) = \text{False}$
- $\text{Tr}(\mathbf{i} \leq \top) = \text{True}$
- $\text{Tr}(\mathbf{i} \leq \sim \mathbf{m}) = x_i^* \preceq y_m$
- $\text{Tr}(\mathbf{i} \leq \sim \mathbf{j}) = x_j \not\preceq x_i^*$
- $\text{Tr}(\mathbf{i} \leq \sim A) = \forall x_j (\text{Tr}(\mathbf{j} \leq A) \rightarrow x_j \not\preceq x_i^*)$
- $\text{Tr}(\mathbf{i} \leq \mathbf{j} \circ \mathbf{k}) = R_{x_j x_k x_i}$
- $\text{Tr}(\mathbf{i} \leq \mathbf{j} \circ B) = \exists x_k (\text{Tr}(\mathbf{k} \leq B) \wedge R_{x_j x_k x_i})$
- $\text{Tr}(\mathbf{i} \leq A \circ B) = \exists x_j (\text{Tr}(\mathbf{j} \leq A) \wedge \text{Tr}(\mathbf{i} \leq \mathbf{j} \circ B))$
- $\text{Tr}(\mathbf{i} \leq A \rightarrow B) = \text{Tr}(\mathbf{i} \circ A \leq B)$
- $\text{Tr}(\mathbf{i} \leq A \leftrightarrow B) = \text{Tr}(A \circ \mathbf{i} \leq B)$
- $\text{Tr}(\mathbf{i} \leq A \Rightarrow B) = \text{Tr}(\mathbf{i} \wedge A \leq B)$
- $\text{Tr}(\mathbf{i} \leq A \wedge B) = \text{Tr}(\mathbf{i} \leq A) \wedge \text{Tr}(\mathbf{i} \leq B)$
- $\text{Tr}(\mathbf{i} \leq A \vee B) = \text{Tr}(\mathbf{i} \leq A) \vee \text{Tr}(\mathbf{i} \leq B)$

Translation rules (Part 2)

- $\text{Tr}(\mathbf{n} \leq \mathbf{m}) = y_m \preceq y_n$
- $\text{Tr}(\mathbf{t} \leq \mathbf{m}) = \neg O_{y_m}$
- $\text{Tr}(\perp \leq \mathbf{m}) = \text{True}$
- $\text{Tr}(\top \leq \mathbf{m}) = \text{False}$
- $\text{Tr}(\sim \mathbf{n} \leq \mathbf{m}) = y_m^* \not\preceq y_n$
- $\text{Tr}(\sim \mathbf{j} \leq \mathbf{m}) = x_j \preceq y_m^*$
- $\text{Tr}(\sim A \leq \mathbf{m}) = \exists x_j (\text{Tr}(j \leq A) \wedge x_j \preceq y_m^*)$
- $\text{Tr}(\mathbf{i} \circ \mathbf{j} \leq \mathbf{m}) = \neg R_{x_i} x_j y_m$
- $\text{Tr}(\mathbf{i} \circ B \leq \mathbf{m}) = \forall x_j (\text{Tr}(j \leq B) \rightarrow \neg R_{x_i} x_j y_m)$
- $\text{Tr}(A \circ B \leq \mathbf{m}) = \forall x_i (\text{Tr}(i \leq A) \wedge \text{Tr}(i \circ B \leq \mathbf{m}))$
- $\text{Tr}(A \Rightarrow B \leq \mathbf{m}) = \forall x_i (\text{Tr}(i \leq A \Rightarrow B) \rightarrow \text{Tr}(i \leq \mathbf{m}))$
- $\text{Tr}(A \rightarrow B \leq \mathbf{m}) = \text{Tr}(A \leq B \vee \mathbf{m})$
- $\text{Tr}(A \wedge B \leq \mathbf{m}) = \text{Tr}(A \leq \mathbf{m}) \vee \text{Tr}(B \leq \mathbf{m})$
- $\text{Tr}(A \vee B \leq \mathbf{m}) = \text{Tr}(A \leq \mathbf{m}) \wedge \text{Tr}(B \leq \mathbf{m})$
- $\text{Tr}(A \leq B) = \forall x_j (\text{Tr}(j \leq A) \rightarrow \text{Tr}(j \leq B))$

The translation Tr is not restricted to pure quasi-inequalities and can be applied to arbitrary pure formulas.

The Python code can be used in any Jupyter notebook, with the output displayed in standard mathematical notation.

No special installation is needed to use the program in a personal Jupyter notebook or in a public cloud-based notebook such as Colab.google.com, and the output can be pasted into standard \LaTeX documents.

Moreover the program can be easily extended to handle the syntax of other suitable logics and lattice-ordered algebras.

Try it out at in a Google Colab notebook

The Python code is available at github.com/jipsen/PEARL

It can also be copied and used directly in a browser at
[https://colab.research.google.com/drive/
1p0PTkmyq7vTWgYDxCTFHVRwjaLeT45uX?usp=sharing](https://colab.research.google.com/drive/1p0PTkmyq7vTWgYDxCTFHVRwjaLeT45uX?usp=sharing).

Two examples of output from the PEARL implementation

- Input: $\text{pearl}((A \rightarrow B) \wedge (B \rightarrow C) \rightarrow (A \rightarrow C), \text{"latex"})$
- Translate to (list of) initial inequalit(ies):
 $[(A \rightarrow B) \wedge (B \rightarrow C) \leq A \rightarrow C]$
- Approximation phase:
 $\mathbf{i} \leq A \rightarrow B, \mathbf{i} \leq B \rightarrow C, \mathbf{j}_1 \rightarrow \mathbf{n}_1 \leq \mathbf{m}, C \leq \mathbf{n}_1, \mathbf{j}_1 \leq A \implies \mathbf{i} \leq \mathbf{m}$
- Order of variables during the elimination phase: $['+A', '+C', '+B']$
- Elimination phase: $\mathbf{j}_1 \rightarrow \mathbf{n}_1 \leq \mathbf{m}, \mathbf{i} \circ (\mathbf{i} \circ \mathbf{j}_1) \leq \mathbf{n}_1 \implies \mathbf{i} \leq \mathbf{m}$
- Apply simplification rules: $\mathbf{i} \circ (\mathbf{i} \circ \mathbf{j}_1) \leq \mathbf{n}_1 \implies \mathbf{i} \leq \mathbf{j}_1 \rightarrow \mathbf{n}_1$
- Apply Tr rules: $\forall x_2 (R_{x_0 x_1 x_2} \implies \neg(R_{x_0 x_2 y_1})) \implies \neg(R_{x_0 x_1 y_1})$
- Contrapose and simplify: $R_{x_0 x_1 y_1} \implies \exists x_2 (R_{x_0 x_1 x_2} \wedge R_{x_0 x_2 y_1})$

Second example

- Input command: `pearl(A → (¬A → B), "latex")`
- Initial inequality after monotone variable elimination: $[A \leq \sim A \rightarrow \perp]$
- Approximation phase:
 $\mathbf{i \leq A, j_1 \rightarrow n_1 \leq m, \perp \leq n_1, j_1 \leq \sim n_2, A \leq n_2 \implies i \leq m}$
- Elimination phase:
 $\mathbf{j_1 \rightarrow n_1 \leq m, \perp \leq n_1, j_1 \leq \sim n_2, i \leq n_2 \implies i \leq m}$
- Apply simplification rules: $\mathbf{j_1 \leq \sim n_2 \implies n_2 \leq j_1 \rightarrow n_1}$
- Apply Tr rules: $\mathbf{x_1^* \preceq y_2 \implies \forall x_2 (R_{x_2 x_1} y_1 \implies x_2 \preceq y_2)}$
